

So when we have a vector product of two vectors,  $\mathbf{A} \times \mathbf{B} = \mathbf{C}$ , let's compute that vector product in different coordinate systems.

So let's begin by choosing two vectors.

$\hat{\mathbf{i}}$ , and  $\hat{\mathbf{j}}$ .

And notice they're at a right angle, and because there is a unit vector, the area here is equal to  $1$ .

And I want to define  $\hat{\mathbf{k}}$  to be equal to  $\hat{\mathbf{i}} \times \hat{\mathbf{j}}$ .

Now, our angle  $\theta$  here was  $90$  degrees.

And so, if I use the right hand rule, then  $\hat{\mathbf{i}} \times \hat{\mathbf{j}}$  is-- the right handed unit normal is out of the plane of the figure.

And so I would write  $\hat{\mathbf{k}}$  like that, and notice  $\hat{\mathbf{k}}$  is out of plane of figure.

And because I used my right hand rule, this is what we call a right handed coordinate system.

Now, there's something very nice about this cross product definition.

Notice that there's a cyclic order.

$\hat{\mathbf{i}}\hat{\mathbf{j}}\hat{\mathbf{k}}$  is a cyclic order.

And if you interchange any two.

For example,  $\hat{\mathbf{j}}\hat{\mathbf{i}}\hat{\mathbf{k}}$ , that's anti-cyclic.

And the cross products satisfy this cyclic rule, in that,  $\hat{\mathbf{j}} \times \hat{\mathbf{k}}$  is  $\hat{\mathbf{i}}$ .

And notice  $\hat{\mathbf{j}}\hat{\mathbf{k}}\hat{\mathbf{i}}$ , maintains that cyclic order, and  $\hat{\mathbf{k}} \times \hat{\mathbf{i}}$  is  $\hat{\mathbf{j}}$ .

$\hat{\mathbf{k}}\hat{\mathbf{i}}\hat{\mathbf{j}}$  maintains that cyclic order, but because of the way we defined a cross-product in general  $\mathbf{A} \times \mathbf{B}$  is minus  $\mathbf{B} \times \mathbf{A}$ , because now you're using the opposite direction, so there's a minus sign.

And therefore, any anti-cyclic permutation of these unit vectors, as an example,  $\hat{\mathbf{k}} \times \hat{\mathbf{j}}$ , has to be-- notice I've-- is minus  $\hat{\mathbf{i}}$ -- that's anti-commutative property of the cross-product.

Similarly,  $\hat{\mathbf{i}} \times \hat{\mathbf{k}}$  is minus  $\hat{\mathbf{j}}$ .

And lastly,  $\hat{j} \times \hat{i}$  is minus  $\hat{k}$ .

And so, in fact, you only need to know one.

And this idea of cyclic, and anti-cyclic, to be able to write down all of the other 6.

So we have one, two, three, four, five, six.

Now, when you want to compute the cross products in Cartesian coordinates, for instance, it can be a little bit messy.

There's going to be a lot of terms.

If I write a vector  $A$  as  $A_x \hat{i} + A_y \hat{j} + A_z \hat{k}$ .

And I write a vector  $B$  as  $B_x \hat{i} + B_y \hat{j} + B_z \hat{k}$ .

And now I want to compute the cross-product of these vectors to get the new one.

Notice that there's going to be six terms, because I have  $\hat{i} \times \hat{i}$ -- well, we actually should say one more thing.

that  $\hat{i} \times \hat{i}$ -- the angle between these two vectors is zero.

There's no perpendicular projection.

So that's zero, as is  $\hat{j} \times \hat{j}$ ,  $\hat{k} \times \hat{k}$ .

So of these nine parts, when we take the cross-product, three of them will be 0, by this rule, and we'll we apply our cyclic or anti-cyclic rules for the others.

And so what we have here-- let's just do it in-- so  $C$  equals  $A \times B$ .

And now let's just go one by one.

$\hat{i} \times \hat{i}$ .

That's 0.

There's no perpendicular part.

The area formed by these two vectors is 0.

$\hat{i} \times \hat{j}$ .

That's cyclic.

$\hat{I}\hat{J}$  is plus  $\hat{K}$ .

So our first non-zero term is  $\hat{A}\hat{X}\hat{B}\hat{Y}\hat{K}\hat{I}\hat{J}$  cross  $\hat{J}$ .

And now let's do  $\hat{I}\hat{J}$  cross  $\hat{K}$ .

Notice that's anti-cyclic.

$\hat{I}\hat{K}$  minus  $\hat{J}$ . So our next term is minus  $\hat{A}\hat{X}\hat{B}\hat{Z}\hat{J}$ .

So there's the first two.

And now let's just continue this process.

$\hat{J}\hat{I}$  cross  $\hat{I}\hat{J}$ .

That's anti-cyclic.

So we have minus  $\hat{A}\hat{Y}\hat{B}\hat{X}\hat{K}$ .

$\hat{A}\hat{Y}\hat{J}$  across  $\hat{B}\hat{X}\hat{I}$ .

$\hat{J}\hat{I}$  cross  $\hat{J}\hat{I}$ .

That's 0.

So we have no contribution there.

And  $\hat{J}\hat{I}$  crossed  $\hat{K}$ , that is cyclic.

So that's plus  $\hat{A}\hat{Y}\hat{B}\hat{Z}\hat{K}$ .

And now we have our last two terms  $\hat{K}\hat{I}$  cross  $\hat{I}\hat{J}$ .

That cyclic.

So that's plus  $\hat{A}\hat{Z}\hat{B}\hat{X}\hat{J}$ .

$\hat{K}\hat{I}$  cross  $\hat{J}\hat{I}$ .

That's anti-cyclic.

So there's a minus  $\hat{i}$  hat.

So it's minus  $\hat{A}Z \hat{B}Y \hat{i}$  hat.

And finally  $\hat{K}$  hat cross  $\hat{K}$  hat, well that's also 0.

So we have six terms.

And we can collect them equal to  $\hat{A}X \hat{B}Y$  minus-- well let's check this one.

Here we used the wrong symbol here.

We have to be a little bit careful here.

$\hat{A}Y$  cross  $\hat{B}Z$  is  $\hat{j}$  hat cross  $\hat{K}$  hat.

That's plus  $\hat{i}$  hat.

So we have  $\hat{A}X\hat{B}Y$  minus  $\hat{A}Y \hat{B}X \hat{K}$  hat.

And now let's look at the  $\hat{i}$  hat terms.

I'll just check those off.

We have  $\hat{A}Y \hat{B}Z$  minus  $\hat{A}Z \hat{B}Y \hat{i}$  hat.

And check those two terms off.

And lastly, we have  $\hat{A}Z \hat{B}X$  minus  $\hat{A}X\hat{B}Z$ .

So we have  $\hat{A}Z\hat{B}X$  minus  $\hat{A}X \hat{B}Z$  and that's  $\hat{j}$  hat.

And that's how we calculate the cross-product in Cartesian coordinates.
